Chapter 9

Homework 3: Independence, Span, Bases, and Linear Systems of Algebraic Equations

Contents

9.1 Linear Independence and Bases	85
9.2 Determinants and Invertibility	85
9.3 Linear Systems of Algebraic Equations: Formulation and Definition	87
9.4 Using Matrix Inverses to Solve Linear Systems	88
9.5 Types of Linear Systems and Types of Solutions	90
9.6 Conceptual Quiz	93

💡 Learning Objectives

Concepts

- Determine for a system of 3 or fewer unknowns whether it has a unique solution, no solution or infinite solutions.
- Create a set of linear equations from a narrative about how the unknown variables are related to given data.
- Represent a system of linear equations with matrix, vector notation
- Solve a linear system of equations

MATLAB skills

- Compute the determinant of a matrix
- Solve systems of linear equations of the form $A\mathbf{x} = \mathbf{b}$ using all three methods: inverse matrix, linsolve, or backslash operator.

mm mm = work
mmmm = Checking Solutions
mmmm = Other

9.1 Linear Independence and Bases

Exercise 9.1

1. Is this set of vectors linearly independent?

$$\begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 2 \\ 0 \end{bmatrix}, \begin{bmatrix} 4 \\ 5 \\ 3 \end{bmatrix} \quad \text{NO} \quad (9.1)$$

2. Please express the vector
- $\begin{bmatrix} 3 \\ 6 \\ 4 \end{bmatrix}$
- as a linear combination of the vectors
- $\begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$

How to solve?
Not orthonormal
Guess?

3. Show that the following vectors form an orthogonal bases for
- \mathbb{R}^4

$$\begin{bmatrix} 1/2 \\ 1/2 \\ 1/2 \\ 1/2 \end{bmatrix}, \begin{bmatrix} 1/2 \\ 1/2 \\ -1/2 \\ -1/2 \end{bmatrix}, \begin{bmatrix} 1/2 \\ -1/2 \\ 1/2 \\ -1/2 \end{bmatrix}, \begin{bmatrix} 1/2 \\ -1/2 \\ -1/2 \\ 1/2 \end{bmatrix} \quad (9.2)$$

$$\begin{aligned} v_1 \cdot v_2 &= \frac{1}{2} - \frac{1}{2} = 0 \\ v_2 \cdot v_3 &= 0 \\ v_3 \cdot v_4 &= 0 \end{aligned}$$

4. Suppose that

$$c_1 \begin{bmatrix} 1/2 \\ 1/2 \\ 1/2 \\ 1/2 \end{bmatrix} + c_2 \begin{bmatrix} 1/2 \\ 1/2 \\ -1/2 \\ -1/2 \end{bmatrix} + c_3 \begin{bmatrix} 1/2 \\ -1/2 \\ 1/2 \\ -1/2 \end{bmatrix} + c_4 \begin{bmatrix} 1/2 \\ -1/2 \\ -1/2 \\ 1/2 \end{bmatrix} = \begin{bmatrix} 5 \\ -2 \\ 0 \\ 1 \end{bmatrix} \quad (9.3)$$

$$\begin{aligned} v_1 \cdot w &= c_1 = 2 \\ v_2 \cdot w &= c_2 = 1 \\ v_3 \cdot w &= c_3 = 4 \\ v_4 \cdot w &= c_4 = 3 \end{aligned}$$

Please find c_1, c_2, c_3 and c_4 . As an aside, these vectors form what is called a Walsh code (which can be expanded to higher dimensions). Walsh codes are used in wireless communications so signals from multiple users can be added together (e.g. at the antenna of a cell tower), and then separated by different mobiles.

5. Construct a
- 4×4
- matrix
- A
- whose columns are the vectors from the previous part. Show that
- c_1, c_2, c_3, c_4
- can be found by solving

$$A = \begin{bmatrix} 1/2 & 1/2 & 1/2 & 1/2 \\ 1/2 & 1/2 & -1/2 & -1/2 \\ 1/2 & -1/2 & 1/2 & -1/2 \\ 1/2 & -1/2 & -1/2 & 1/2 \end{bmatrix} \quad A \begin{bmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \end{bmatrix} = \begin{bmatrix} 5 \\ -2 \\ 0 \\ 1 \end{bmatrix} \Rightarrow \text{Invert of A?}$$

max result
this was?

9.2 Determinants and Invertibility

You have already encountered the determinant in class: the determinant of a square matrix is a property of the matrix which among other things indicates whether a matrix is invertible or not: if the determinant of a square matrix is zero, it is non-invertible. As a reminder:

The determinant of a matrix \mathbf{G} is denoted a few different ways.

$$\det(\mathbf{G}) = |\mathbf{G}| \quad (9.9)$$

For a generic 2×2 matrix \mathbf{G}

$$\mathbf{G} = \begin{bmatrix} a & b \\ c & d \end{bmatrix},$$

the formula for the determinant is quite straightforward:

$$\det(\mathbf{G}) = ad - bc \quad (9.10)$$

For example, for the following 2×2 matrix,

$$\begin{aligned} \det \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix} &= \begin{vmatrix} 1 & 2 \\ 3 & 4 \end{vmatrix} \\ &= (1)(4) - (2)(3) = -2 \end{aligned} \quad (9.11)$$

You already considered the determinant of some transformation matrices, now let's consider what the determinant is really telling us about a general matrix.

Exercise 9.2

1. Let \mathbf{A} be a 2×2 matrix

$$\mathbf{A} = \begin{bmatrix} x_1 & x_2 \\ y_1 & y_2 \end{bmatrix}.$$

We can think of the columns of \mathbf{A} as two vectors beginning at the origin and ending at the points (x_1, y_1) and (x_2, y_2) , respectively. These vectors form a parallelogram, as shown here:

Handwritten notes:
 $A = x_1 \cdot y_2$
 This would appear to be wrong
 Correct: $ad - bc = \det(A)$

Show that the magnitude (i.e., absolute value) of $\det(\mathbf{A})$ is equal to the area of a parallelogram formed by the column vectors of the matrix \mathbf{A} .

2. What is the determinant of \mathbf{A} if its column vectors are on the same line? Graphically, what happens to the parallelogram?

From this, you should get the feeling for the fact that the determinant is a measure of how co-linear the columns of \mathbf{A} are: or in other words, how linearly independent the two columns are. The determinant therefore lets us know quickly if a linear system of algebraic equations has a solution, as illustrated in the following example.

Exercise 9.3

Consider the following matrix whose columns lie on the same line: the second column is simply

twice the first column.

$$\mathbf{A} = \begin{bmatrix} 1 & 2 \\ 2 & 4 \end{bmatrix} \quad (9.12)$$

1. What is $\det(\mathbf{A})$?
2. Find all the solutions to $\mathbf{Ax} = \mathbf{0}$.
3. For which vectors \mathbf{b} does $\mathbf{Ax} = \mathbf{b}$ have a solution? Why are there only certain \mathbf{b} vectors that lead to solutions to $\mathbf{Ax} = \mathbf{b}$?

Handwritten notes:

- For question 1: $\det(\mathbf{A}) = 0$
- For question 2: $\begin{bmatrix} 1 & 2 \\ 2 & 4 \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix} = \begin{bmatrix} a+2b \\ 2a+4b \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$
 - $a+2b=0 \Rightarrow a=-2b$
 - $2a+4b=0 \Rightarrow a+2b=0$
- For question 3: $\begin{bmatrix} x_1+2x_2 \\ 2x_1+4x_2 \end{bmatrix} = \mathbf{b}$
 - $\Rightarrow b_2$ must be $2 \times b_1$

While the formula for the determinant of a 2×2 matrix is quite straightforward, the procedures for computing the determinant of larger matrices is more difficult, but they are well known and well documented. Fortunately, MATLAB has the `det` function which computes the determinant.

9.3 Linear Systems of Algebraic Equations: Formulation and Definition

In previous classes, you've encountered a bunch of exercises where you had to operate on a vector to find another vector:

$$\mathbf{Ax} = \mathbf{b}, \quad (9.13)$$

where \mathbf{A} and \mathbf{x} were known, and your job was to find \mathbf{b} . While this is fun and, as you saw above in the rectangle exercise, can be useful, there is another related problem which is easily as important. It involves the same equation, but now you know \mathbf{A} and \mathbf{b} and need to find the vector \mathbf{x} . As we will discuss here, this problem captures the concept of a Linear System of Algebraic Equations.

One key idea in building models is the step of abstraction: going from some real-world situation to an abstracted model for the system (e.g., a set of equations). There are two important aspects of building such a model: first, deciding what to include or ignore, and second, deciding how to mathematically represent those things you choose to include.

One particularly common kind of mathematical framing is a set of linear algebraic equations, which can be represented by a matrix equation. A general system of m linear algebraic equations in n unknown variables x_1, x_2, \dots, x_n takes the form

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \dots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 + \dots + a_{2n}x_n &= b_2 \\ &\dots \\ a_{m1}x_1 + a_{m2}x_2 + a_{m3}x_3 + \dots + a_{mn}x_n &= b_m \end{aligned}$$

where $a_{11}, a_{12}, \dots, a_{mn}$ are known as coefficients and $b_1, b_2, b_3, \dots, b_m$ are constants. We can write this using matrices and vectors in the form

$$\mathbf{Ax} = \mathbf{b}$$

where \mathbf{A} is the $m \times n$ coefficient matrix, \mathbf{x} is the $n \times 1$ unknown vector, and \mathbf{b} is a $m \times 1$ constant vector which is known. In other words,

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{bmatrix}, \quad \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}, \quad \mathbf{b} = \begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_m \end{bmatrix}.$$

Note that “linear” here means linear in terms of the unknown variables, e.g., if x is an unknown there are only terms like ax , and no terms like $\sin(x)$, x^2 , $1/x$, etc. It is often the case that you might have coefficients that appear to be non-linear; for example, in solving physics problems, you might have coefficients that depended on trig functions of angles, such as $(L \cos \theta)F_x$, which is linear in F_x but not linear in θ . Be careful to be clear about what you’re solving for when you decide whether something is linear or non-linear.

9.4 Using Matrix Inverses to Solve Linear Systems

Over the last couple of weeks, you have worked with rotation matrices, and transformations that were compositions of simpler rotations, and learned how to invert them. When you multiply a vector by any matrix (not just ones that are associated with simple spatial transformations), you transform the original vector x into a new vector b .

$$Ax = b$$

More generally (than rotations), you can *often* undo the linear transformation (just like you did with the rotation matrix). Undoing this linear transformation is a linear transformation itself! Therefore the act of undoing a linear transformation can be formulated with a matrix multiply.

$$\begin{aligned} A^{-1}Ax &= A^{-1}b \\ \Rightarrow x &= A^{-1}b \end{aligned}$$

This reduces our linear system of algebraic equations problem to the problem of finding the inverse of our matrix A . Note this is only possible if A is square and invertible.

When solving a system of equations, at least half of the battle is typically getting your system abstracted to the point that it can be thought of as a system of linear equations. The following are a set of problems. You don’t need to solve these problems – you just need to formulate them as linear algebra problems.

An Investment Example

In this section we will focus on deciding whether and how you can abstract the system to a mathematical model that can be written as a matrix equation.

Exercise 9.4

Suppose that the following table describes the stock holdings of three of the QEA instructors. Also suppose that on a given day the value of the Apple, IBM and General Mill’s stock are \$100, \$50 and \$20 respectively.

	Apple	IBM	General Mills
Paul	100	100	100
Siddhartan	100	200	0
John	50	50	200

- Here’s your first linear algebra formulation question: What is the total value of the holdings for each professor on the day in question? Can you formulate this as a matrix expression? If so, what is it? If not, why not?
- Now, suppose that you do not know how many shares of each stock are owned by the instructors. However, you know that the total value of the stocks for each instructor for three consecutive days is as given in the following table

Handwritten notes and matrices:

Handwritten labels above the table: #Apple, #IBM, #GMills, \$

Handwritten matrix for holdings (from the table):

$$\begin{bmatrix} 100 & 100 & 100 \\ 100 & 200 & 0 \\ 50 & 50 & 200 \end{bmatrix}$$

Handwritten matrix for stock values:

$$\begin{bmatrix} 100 \\ 50 \\ 20 \end{bmatrix}$$

Handwritten equation:

$$\begin{bmatrix} 100 & 100 & 100 \\ 100 & 200 & 0 \\ 50 & 50 & 200 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 100 \\ 50 \\ 20 \end{bmatrix}$$

Handwritten vector on the right:

$$\begin{bmatrix} 100 \\ 50 \\ 20 \end{bmatrix}$$

	Paul	Siddhant	John
Day 1	\$1500	\$2600	\$950
Day 2	\$1600	\$2810	\$1020
Day 3	\$1400	\$2550	\$1000

You also know that the price of each stock on each of the three days was as follows:

	Apple	IBM	General Mills
Day 1	\$100	\$50	\$20
Day 2	\$110	\$50	\$22
Day 3	\$100	\$40	\$30

Now here's the second formulation question: how many stocks of each company does each professor own? Can you formulate this as a matrix equation? If so, what are the matrices/vectors? If not, why not?

~~NO: this would be a 3D matrix, which we can't handle~~

~~Prof | Apple | IBM | General Mills~~
~~times~~ ~~P~~ ~~I~~ ~~J~~ =

Day | P | I | J
 1 | | |
 2 | | |
 3 | | |

Nope! # of shares used doesn't change!

Let's now look at an example involving flows. In this case, we are looking at traffic flows on streets, and in and out of junctions. Similar ideas are applicable in many situations, including fluid flow in pipes, currents flowing in circuits, data packets in computer networks, etc.

Exercise 9.5

A portion of the roads in Gotham, which are organized in a grid of one way streets, is illustrated in the following figure

$$\begin{bmatrix} f_1 & f_2 & f_3 & f_4 & f_5 & f_6 & f_7 & f_8 & f_9 & f_{10} \\ 1 & 1 & -1 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & -1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 & -1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} f_1 \\ f_2 \\ f_3 \\ f_4 \\ f_5 \\ f_6 \\ f_7 \\ f_8 \\ f_9 \\ f_{10} \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{aligned} f_1 + f_2 &= f_{10} + f_3 \\ f_3 &= f_5 + f_4 \\ f_8 + f_{10} &= f_9 \\ f_4 + f_6 &= f_8 + f_7 \\ f_2 &= 1 \\ f_5 &= 3, f_7 = 1 \\ f_6 &= 3, f_9 = 2 \end{aligned}$$

Let the average traffic flow on the roads and into/out of the intersections be denoted by f_1, f_2, \dots, f_{10} in units of cars per minute. Suppose that in the green future, few people drive cars and $f_2 = 1, f_5 = 3, f_6 = 3, f_7 = 1, f_9 = 2$. Assume that the total traffic flow into each intersection equals the total traffic flow out of the intersection, i.e. there is no buildup of vehicles in any intersection.

- Set up a system of linear equations in matrix vector form which describes the relationships between all the flows.
- With the information given, are you able to solve for the unknown flows? If so, please write a matrix-vector equation to solve for the remaining flows and solve for them using MATLAB.

NO

3. Suppose that we know that $f_3 = 2$? Please write a matrix-vector equation to solve for the remaining flows, and solve for them using MATLAB. *see attached*
4. (Bonus question worth zero points): If the arrows above represent "one way" traffic signs, which one(s) is/are pointing in the wrong direction(s)? *f4*

9.5 Types of Linear Systems and Types of Solutions

Consider the linear system of algebraic equations expressed in matrix-vector form as,

$$\mathbf{Ax} = \mathbf{b}.$$

If $\mathbf{b} = \mathbf{0}$ the system of linear algebraic equations is *homogeneous* and if $\mathbf{b} \neq \mathbf{0}$ the system is *non-homogeneous*. As mentioned before, we've already dealt with systems like this before when we were transforming geometrical objects, but in that case we already knew \mathbf{x} and we were simply multiplying by \mathbf{A} in order to get \mathbf{b} . Here, we are considering the so-called *inverse* problem, and trying to find \mathbf{x} given \mathbf{A} and \mathbf{b} . However, let's back up and consider some small examples to explore the solution possibilities a little. *homogeneous?*

Elimination of Variables

In high school you probably learned some basic techniques for solving small linear systems of algebraic equations. Consider the following linear system of algebraic equations,

$$2x_1 + 3x_2 = 6 \quad (9.29)$$

$$4x_1 + 9x_2 = 15 \quad (9.30)$$

The basic technique, called *elimination of Variables*, proceeds as follows: First, solve equation (2) for x_1

$$x_1 = 3 - \frac{3}{2}x_2 \quad (9.31)$$

Now substitute this expression for x_1 into equation (3)

$$4\left(3 - \frac{3}{2}x_2\right) + 9x_2 = 15$$

Now we simplify this equation

$$\begin{aligned} 12 - 6x_2 + 9x_2 &= 15 \\ \Rightarrow 3x_2 &= 3 \end{aligned}$$

and solve for x_2 to give $x_2 = 1$. Now we substitute this solution back into equation (2) or (4) to determine $x_1 = \frac{3}{2}$. The original linear system of algebraic equations therefore has a unique solution, $\mathbf{x} = \begin{bmatrix} 1 \\ 3/2 \end{bmatrix}$.

However, not all linear systems of algebraic equations have a unique solution. For example, the system

$$x_1 + 2x_2 = 1 \quad (9.32)$$

$$2x_1 + 4x_2 = 2 \quad (9.33)$$

has an infinite number of solutions because equation (6) is just a multiple of equation (5). Solving equation (5) for x_1 gives

$$x_1 = 1 - 2x_2$$

and choosing an arbitrary value of $x_2 = \alpha$ gives

$$\begin{aligned}x_1 &= 1 - 2\alpha \\x_2 &= \alpha\end{aligned}$$

or in vector form

$$\mathbf{x} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} + \alpha \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

This defines an infinite number of solutions since α is any real number. What do you notice about each part of this vector?

It's also possible that a linear system of algebraic equations has no solution. For example, the system

$$x_1 + 2x_2 = 1 \quad (9.34)$$

$$2x_1 + 4x_2 = 1 \quad (9.35)$$

has no solution. Solving equation (8) for x_2 gives

$$x_2 = \frac{1}{4} - \frac{1}{2}x_1$$

and replacing into equation (7) gives

$$x_1 + 2\left(\frac{1}{4} - \frac{1}{2}x_1\right) = 1$$

which on simplification gives

$$\frac{1}{2} = 1$$

which hopefully we all agree is incorrect. We assumed that there was a solution, performed elimination and substitution and found a statement that contradicts our assumption: no solution therefore exists.

Exercise 9.6

- Using the technique of elimination of variables described above, determine which values of h and k result in the following system of linear algebraic equations having (a) no solution, (b) a unique solution, and (c) infinitely many solutions?

a) $h=1.5, k \neq 2$

b) $h \neq 1.5$

c) $h=1.5, k=2$

$$x_1 + hx_2 = 1$$

$$2x_1 + 3x_2 = k$$

$$x_1 = 1 - hx_2$$

$$2 - 2hx_2 + 3x_2 = k$$

- Using the technique of elimination of variables described above, determine whether the following linear systems of algebraic equations have zero, one, or infinitely many solutions. If solution(s) exist, determine the actual solution(s).

(a)

$$\mathbf{x} = \begin{bmatrix} 4 \\ 2 \\ 0 \end{bmatrix}$$

$$x_1 + x_2 + x_3 = 6$$

$$x_2 + x_3 = 2$$

$$x_1 - 2x_3 = 4$$

$$6 + 2x_3 = 6 \Rightarrow x_3 = 0$$

$$4 + 2x_3 + 2 - x_3 + x_3 = 6$$

$$x_2 = 2 - x_3 \Rightarrow x_2 = 2$$

$$x_1 = 4 + 2x_3 \Rightarrow x_1 = 4$$

(b)

$$x_1 + x_2 + x_3 = -6$$

$$2x_1 + x_2 - x_3 = 18$$

$$x_1 - 2x_3 = 4$$

$$-x_1 + 2x_3 = -24 \Rightarrow \emptyset$$

$$x_1 = 4 + 2x_3$$

(c)

$$\begin{aligned}
 -x_1 + 2x_3 &= -4 & \text{I can't figure out how to prove this, but it has no solutions.} \\
 x_1 + x_2 + x_3 &= 6 \\
 2x_1 + x_2 - x_3 &= 10 & x_3 = -10 + x_2 + 2x_1 \\
 x_1 - 2x_3 &= 4 & x_1 = 4 + 2x_3
 \end{aligned}$$

Solving a linear system of algebraic equations in MATLAB

Exercise 9.7

In the last class, you worked with an example of fruits in your refrigerator, and we asked you questions like how to calculate the total weight of the fruits, how many fruits there are, etc. We can use matrix operations to calculate *inverse problems* as well, as this question illustrates. Suppose that you know that you have apples and oranges in the fridge and that in the genetically engineered future, the weights of all apples are 3oz and all oranges are 4oz. Because of inflation in this genetically engineered future, the price of each apple is \$1 and the price of each orange is \$2. Suppose that you also know that you paid \$13 total for your fruit and the total weight of the fruit is 33 oz. We can use this information and tools we have developed to figure out how many apples and oranges we have. Let n_o and n_a be the numbers of oranges and apples in your fridge respectively, and that you don't know what these numbers are. Define the following vectors

$$\mathbf{n} = \begin{bmatrix} n_o \\ n_a \end{bmatrix} \quad (9.36)$$

$$\mathbf{d} = \begin{bmatrix} 13 \\ 33 \end{bmatrix} \quad (9.37)$$

- Write an equation relating \mathbf{n} and \mathbf{d} , using a matrix-vector product.
- Calculate how many oranges and apples you have.
- Why this kind of problem is often called an inverse problem?

$$\begin{bmatrix} 2 & 1 \\ 4 & 3 \end{bmatrix} \begin{bmatrix} n_o \\ n_a \end{bmatrix} = \begin{bmatrix} 13 \\ 33 \end{bmatrix}$$

you must invert the equation (2 matrix)

Exercise 9.8

- Consider the example with the fruits that you worked out earlier. Now, in addition to apples and oranges, suppose you also had an unknown number of pears which each weigh 3 oz, and cost \$3. Additionally, suppose that the total weight of the fruits is 45 oz, and you paid a total of \$21 for the fruit.

3 unknowns 2 equations

- If possible find the numbers of oranges, apples and pears. If not, please explain why.
- Suppose that you additionally know that you have a total of 14 fruits. Can you formulate and solve a matrix-vector equation to find out the numbers of oranges, apples and pears you have?

$$\begin{bmatrix} 2 & 1 & 3 \\ 4 & 3 & 3 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} n_o \\ n_a \\ n_p \end{bmatrix} = \begin{bmatrix} 21 \\ 45 \\ 14 \end{bmatrix} \Rightarrow \begin{bmatrix} 3 \\ 9 \\ 2 \end{bmatrix}$$

- (c) What is the determinant of the matrix you have set up to solve this? 2
2. The fruit vendors bought the pricing algorithm from Uber. Oranges are still \$2, pears are now only \$1.50, and (due to an influx of teachers) apples are now surging at \$1.50 each. Their weights stay the same. You return to the market, and again purchase 14 fruits, which have the same total weight and total cost.
- (a) Can you formulate and solve a matrix-vector equation to find out the numbers of oranges, apples and pears you have? *NO: Pears vs. apples ambiguous*
- (b) What is the determinant of the matrix you have set up to solve this? 0
3. Recall the example with fruits from class: Suppose that you have a total number of 14 apples, oranges and pears in your fridge. Suppose that each apple costs \$1, each orange costs \$2 and each pear costs \$3. Assume also that the weights of every apple is 3 oz, every orange is 4 oz and every pear is 3 oz. Additionally, suppose that the total weight of the fruits is 45 oz, and you paid a total of \$21 for the fruit.
- (a) Formulate (or look up your formulation from class) and write down (but don't solve it yet) a matrix-vector equation to find out the numbers of oranges, apples and pears you have.
- (b) Solve this equation to find the numbers of apples, oranges and pears using the following approaches (they will of course give you the same results, but we want you to get familiar with using the different operations here).
- Using MATLAB, compute the inverse of the matrix in part a and use it to find the numbers of apples, oranges and pears.
 - Use MATLAB's `linsolve` function to find the numbers of apples, oranges and pears.
 - Use MATLAB's `\` operator to find the numbers of apples, oranges and pears.

$$\begin{bmatrix} 2 & 1.5 & 1.5 \\ 4 & 3 & 3 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} n_o \\ n_a \\ n_p \end{bmatrix} = \begin{bmatrix} 21 \\ 45 \\ 14 \end{bmatrix} \Rightarrow \begin{bmatrix} \\ \\ \end{bmatrix}$$

9.6 Conceptual Quiz

1. Select the matrices which are invertible.

(a) $\begin{bmatrix} 2 & 3 \\ 1 & 4 \end{bmatrix}$

(b) $\begin{bmatrix} 1 & 0 \\ 1 & 0 \end{bmatrix}$

(c) $\begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$

(d) $\begin{bmatrix} 1 & 2 \\ 4 & 8 \end{bmatrix}$

(e) $\begin{bmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix}$

2. How many solutions does the following system of equations have?

$$x + y = 9$$

$$\begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & -1 \\ 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 9 \\ 2 \\ 7 \end{bmatrix}$$

$$x - z = 2$$

$$y + z = 7$$

- ☒ A. Zero
☐ B. One
☐ C. Two
☐ D. infinitely many

3. What is the area of a parallelogram whose vertices are $(0, 0)$, $(2, 4)$, $(5, 1)$ and $(7, 5)$?

4. Solve the following system of linear equations

$$\begin{vmatrix} 2 & 5 \\ 4 & 1 \end{vmatrix} = 2 - 20 = -18$$

What is the value of y ?

$$x - y = 2$$

$$3x + z = 11$$

$$y - 2z = -3$$

$$y = x - 2$$

$$z = 11 - 3x$$

$$y = -3 + 2z$$

$$x - 2 = -3 + 2z$$

$$x - 2 = -3 + 2z - 6x$$

$$7x = 21$$

$$x = 3$$

$$y = 1$$

$$a = \sqrt{3^2 + 1^2}$$

$$a = \sqrt{26}$$

$$b = \sqrt{2^2 + 4^2}$$

$$= \sqrt{20}$$

Solution 9.1

1. No, because

$$3 \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} 1 \\ 2 \\ 0 \end{bmatrix} - \begin{bmatrix} 4 \\ 5 \\ 3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \quad (9.5)$$

- 2.

$$\begin{bmatrix} 3 \\ 6 \\ 4 \end{bmatrix} = 2 \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} + 3 \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} \quad (9.6)$$

- 3.

$$\begin{bmatrix} \frac{1}{2} & \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} \frac{1}{2} \\ \frac{1}{2} \\ -\frac{1}{2} \\ -\frac{1}{2} \end{bmatrix} = 0$$

$$\begin{bmatrix} \frac{1}{2} & \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} \frac{1}{2} \\ -\frac{1}{2} \\ \frac{1}{2} \\ -\frac{1}{2} \end{bmatrix} = 0$$

$$\begin{bmatrix} \frac{1}{2} & \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} \frac{1}{2} \\ -\frac{1}{2} \\ -\frac{1}{2} \\ \frac{1}{2} \end{bmatrix} = 0$$

$$\begin{bmatrix} \frac{1}{2} & \frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} \end{bmatrix} \begin{bmatrix} \frac{1}{2} \\ \frac{1}{2} \\ -\frac{1}{2} \\ -\frac{1}{2} \end{bmatrix} = 0$$

$$\begin{bmatrix} \frac{1}{2} & \frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} \end{bmatrix} \begin{bmatrix} \frac{1}{2} \\ -\frac{1}{2} \\ \frac{1}{2} \\ -\frac{1}{2} \end{bmatrix} = 0$$

$$\begin{bmatrix} \frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} \frac{1}{2} \\ \frac{1}{2} \\ -\frac{1}{2} \\ \frac{1}{2} \end{bmatrix} = 0$$

Note that when you expand out each product of the row and column vectors above, you get a sum of two $\frac{1}{4}$ terms and two $-\frac{1}{4}$ terms, resulting in zero. Therefore, the vectors are all orthogonal to each other.

4. We have already proven that the vectors in this question are mutually orthogonal in the previous part. Additionally, note that they are all of unit length, and they span \mathbf{R}^4 , because they are 4 mutually orthogonal, 4-dimensional vectors. To find c_1, c_2, c_3, c_4 , we can do the

following:

$$\begin{aligned} c_1 &= \begin{bmatrix} \frac{1}{2} & \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} 5 \\ -2 \\ 0 \\ 1 \end{bmatrix} = 2 \\ c_2 &= \begin{bmatrix} \frac{1}{2} & \frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} \end{bmatrix} \begin{bmatrix} 5 \\ -2 \\ 0 \\ 1 \end{bmatrix} = 1 \\ c_3 &= \begin{bmatrix} \frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} & \frac{1}{2} \end{bmatrix} \begin{bmatrix} 5 \\ -2 \\ 0 \\ 1 \end{bmatrix} = 4 \\ c_4 &= \begin{bmatrix} \frac{1}{2} & -\frac{1}{2} & \frac{1}{2} & -\frac{1}{2} \end{bmatrix} \begin{bmatrix} 5 \\ -2 \\ 0 \\ 1 \end{bmatrix} = 3 \end{aligned} \quad (9.7)$$

5. Let's write

$$\begin{bmatrix} \frac{1}{2} & \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} & -\frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & -\frac{1}{2} & \frac{1}{2} & -\frac{1}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \end{bmatrix} = \begin{bmatrix} 5 \\ -2 \\ 0 \\ 1 \end{bmatrix} \quad (9.8)$$

If we expand out the equation above according to the rules of matrix-vector multiplication, we get (9.3). Therefore, by solving it, we can find c_1, c_2, c_3 and c_4 .

Solution 9.2

1.

2.

3. The determinant is equal to 0, or $\det(\mathbf{A})=0$.

Solution 9.3

1. $\det(\mathbf{A})=(1)(4)-(2)(2)=0$

2. There are infinitely many solutions of the form $-x_1 = 2x_2$.

3. Solutions are of the form $\mathbf{b} = \begin{bmatrix} k \\ 2k \end{bmatrix}$ where k is a constant.

Solution 9.4

1. This can be formulated as $\mathbf{Ax} = \mathbf{b}$ where

$$\mathbf{A} = \begin{bmatrix} 100 & 100 & 100 \\ 100 & 200 & 0 \\ 50 & 50 & 200 \end{bmatrix}, \mathbf{x} = \begin{bmatrix} 100 \\ 50 \\ 20 \end{bmatrix}, \text{ and } \mathbf{b} = \begin{bmatrix} d_{pr} \\ d_{sg} \\ d_{jg} \end{bmatrix}.$$

Doing the matrix multiplication shows that Paul has $d_{pr} = 17000$, Siddharta has $d_{sg} = 20000$, and John has $d_{jg} = 11500$.

2. There are several ways to do this. Perhaps the simplest is to compute each person's stock holding individually. To do this, we let \mathbf{A} be a matrix with the stock prices

$$\mathbf{A} = \begin{bmatrix} 100 & 50 & 20 \\ 110 & 50 & 22 \\ 100 & 40 & 30 \end{bmatrix},$$

let \mathbf{b}_{pr} be a vector representing the value of Paul's stocks on each day,

$$\mathbf{b}_{pr} = \begin{bmatrix} 1500 \\ 1600 \\ 1400 \end{bmatrix},$$

and let \mathbf{x}_{pr} be a vector representing Paul's stock holdings (i.e., the first entry tells us how many stocks of Apple he has, the second entry is IBM, and the third is General Mills). This gives the equation $\mathbf{Ax}_{pr} = \mathbf{b}_{pr}$. By inverting \mathbf{A} we can solve for \mathbf{x}_{pr} . Then we repeat this procedure for each of the other instructors.

But... we can do it quicker! Form a 3×3 matrix \mathbf{X} whose columns are made the vectors \mathbf{x}_{pr} , \mathbf{x}_{sg} , and \mathbf{x}_{jg} . Then form a 3×3 matrix \mathbf{B} whose columns are made of the vectors \mathbf{b}_{pr} , \mathbf{b}_{sg} , and \mathbf{b}_{jg} . This gives the equation $\mathbf{AX} = \mathbf{B}$. Inverting \mathbf{A} , we can solve for \mathbf{X} :

	Paul	Siddharta	John
Apple	10	20	5
IBM	10	10	5
General Mills	0	5	10

Solution 9.5

1. Let's sum all the flows into each junction. We therefore have

$$f_1 + f_2 = f_3 + f_10 \quad (9.14)$$

$$f_3 = f_4 + f_5 \quad (9.15)$$

$$f_7 + f_8 = f_4 + f_6 \quad (9.16)$$

$$f_9 = f_{10} + f_8 \quad (9.17)$$

Substituting the known information and rearranging gives us

$$f_1 - f_3 - f_{10} = -1 \quad (9.18)$$

$$f_3 - f_4 = 3 \quad (9.19)$$

$$f_8 - f_4 = 2 \quad (9.20)$$

$$f_8 + f_{10} = 2 \quad (9.21)$$

So we can then write a matrix vector equation

$$\begin{bmatrix} 1 & -1 & 0 & 0 & -1 \\ 0 & 1 & -1 & 0 & 0 \\ 0 & 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} f_1 \\ f_3 \\ f_4 \\ f_8 \\ f_{10} \end{bmatrix} = \begin{bmatrix} -1 \\ 3 \\ 2 \\ 2 \end{bmatrix} \quad (9.22)$$

2. You cannot solve for the variables since an 4×5 matrix is not invertible.

3. In this case, the equations become

$$f_1 - f_{10} = 1 \quad (9.23)$$

$$f_4 = -1 \quad (9.24)$$

$$f_8 - f_4 = 2 \quad (9.25)$$

$$f_8 + f_{10} = 2 \quad (9.26)$$

So we can then write a matrix vector equation

$$\begin{bmatrix} 1 & 0 & 0 & -1 \\ 0 & 1 & 0 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} f_1 \\ f_4 \\ f_8 \\ f_{10} \end{bmatrix} = \begin{bmatrix} 1 \\ -1 \\ 2 \\ 2 \end{bmatrix} \quad (9.27)$$

We can check the determinant of the matrix in the equation above in MATLAB, to find that it equals 1. Therefore, we can solve for f_1, f_4, f_8, f_{10} by inverting the matrix as follows

$$\begin{bmatrix} f_1 \\ f_4 \\ f_8 \\ f_{10} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & -1 \\ 0 & 1 & 0 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & 1 & 1 \end{bmatrix}^{-1} \begin{bmatrix} 1 \\ -1 \\ 2 \\ 2 \end{bmatrix} \quad (9.28)$$

The MATLAB code to solve this problem is:

```
» A = [1 0 0 -1 ; 0 1 0 0; 0 -1 1 0; 0 0 1 1] % setup the
matrix
» det(A) % check determinant
» b = [1; -1; 2; 2] % setup vector of known values
» inv(A)*b % solve for the unknowns
```

4. The arrow for f_4 is pointing the wrong way as the solution above has f_4 as a negative number.

Solution 9.6

1. Rearrange the equations to linear form $y = mx + b$. If the lines are identical, there are infinitely many solutions; if the lines are parallel, but don't overlap, there are zero solutions; if the lines are not parallel, there is one solution.

(a) $h=3/2, k \neq 2$,

(b) $h \neq 3/2$,

(c) $h=3/2, k=2$

2. (a) $x = \begin{bmatrix} 4 \\ 2 \\ 0 \end{bmatrix}$

(b) No Solution

(c) Infinite Solutions

Solution 9.7

1. $\begin{bmatrix} 2 & 1 \\ 4 & 3 \end{bmatrix} \begin{bmatrix} n_o \\ n_a \end{bmatrix} = \begin{bmatrix} 13 \\ 33 \end{bmatrix}$

2. $\begin{bmatrix} n_o \\ n_a \end{bmatrix} = \begin{bmatrix} 3 \\ 7 \end{bmatrix}$

3. In this case we know the result b, and are working backwards to find the number of apples and oranges. We also use a matrix inverse to find the result.

Solution 9.8

1. (a) No, you have three unknowns and only two equations.
 (b) Yes, you now have three equations and three unknowns.

$$\begin{bmatrix} 2 & 1 & 3 \\ 4 & 3 & 3 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} n_o \\ n_a \\ n_p \end{bmatrix} = \begin{bmatrix} 21 \\ 45 \\ 14 \end{bmatrix}$$

$$\begin{bmatrix} n_o \\ n_a \\ n_p \end{bmatrix} = \begin{bmatrix} 3 \\ 9 \\ 2 \end{bmatrix}$$

(c) $\det(\mathbf{A}) = 2$

2. (a)

$$\begin{bmatrix} 2 & 1.50 & 1.50 \\ 4 & 3 & 3 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} n_o \\ n_a \\ n_p \end{bmatrix} = \begin{bmatrix} 21 \\ 45 \\ 14 \end{bmatrix}$$

This formulation cannot be solved because \mathbf{A} is not invertible.

(b) $\det(\mathbf{A}) = 0$

3. (a)

$$\begin{bmatrix} 2 & 1 & 3 \\ 4 & 3 & 3 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} n_o \\ n_a \\ n_p \end{bmatrix} = \begin{bmatrix} 21 \\ 45 \\ 14 \end{bmatrix}$$

- (b) i.

$$\begin{bmatrix} n_o \\ n_a \\ n_p \end{bmatrix} = \begin{bmatrix} 3 \\ 9 \\ 2 \end{bmatrix}$$

- ii.

$$\begin{bmatrix} n_o \\ n_a \\ n_p \end{bmatrix} = \begin{bmatrix} 3 \\ 9 \\ 2 \end{bmatrix}$$

- iii.

$$\begin{bmatrix} n_o \\ n_a \\ n_p \end{bmatrix} = \begin{bmatrix} 3 \\ 9 \\ 2 \end{bmatrix}$$
